1 Nash Equilibria **1**

1.A Matrix A 1

1.B Matrix B 2

1.C Matrix C 2

2 Hot-dog Vendors **2**

3 Constructing Games **3**

4 Nash Equilibrium Statements **4**

5 Parameterized Payoff Matrix **4**

1 Nash Equilibria

1.A) Matrix A

Problem. Find all pure strategy Nash equilibria in the game below. In the payoff matrix below the rows correspond to player A's strategies and the columns correspond to player B's. The first entry in each box is player A's payoff and the second entry is player B's payoff.

	B Left	B Right
A Up	(1, 2)	(3, 2)
A Down	(2, 4)	(0, 2)

Solution. Player A's best response to B's Left is Down, while A's best response to B's Right is Up. Player B's best response to A's Up is either Left or Right (the payoffs tie), and B's best response to A's Down is Left. So the pure-strategy Nash equilibria are (Down, Left) and (Up, Right).

1.B) Matrix B

Problem. Consider the two-player game with players, strategies and payoffs described in the following game matrix.

1. Does either player have a dominant strategy? Explain briefly (1-3 sentences).
2. Find all pure strategy Nash equilibria for this game.

	B Left	B Middle	B Right
A Top	(0, 3)	(6, 2)	(1, 1)
A Middle	(2, 3)	(0, 1)	(7, 0)
A Bottom	(5, 3)	(4, 2)	(3, 1)

Solution. Player A's has a dominant strategy of Bottom, since it gives A a higher payoff than either alternative for every strategy of B. Player B has no dominant strategy. The unique pure-strategy Nash equilibrium is (Bottom, Left).

1.C) Matrix C

Problem. Consider the following two-player game in which each player has three strategies. Find all the pure strategy Nash equilibria for this game.

	B Left	B Middle	B Right
A Up	(1, 1)	(2, 3)	(1, 6)
A Middle	(3, 4)	(5, 5)	(2, 2)
A Down	(1, 10)	(4, 7)	(0, 4)

Solution. A's best response to each of B's strategies is Middle. B's best responses to A's strategies Up is Right, Middle is Middle, and Down is Left, respectively. So the unique pure-strategy Nash equilibrium is (Middle, Middle).

2 Hot-dog Vendors

Problem. Consider a football stadium with three seating sections, S_1, S_2, and S_3, arranged in a row. The distance between S_1 and S_2 is the same as the distance between S_2 and S_3. Each section seats 100 people.

Two hotdog vendors must choose a section in which to set up shop. Fans do not want to miss any part of the game, so each fan buys a hotdog from the vendor in the closest section; assume the fan's location within a section does not affect distance. Every seat is occupied, and every fan buys one hotdog. If a fan is equally far from both vendors, that fan is split evenly between them. For example, if the vendors choose S_1 and S_3, half the fans in S_2 buy from each vendor. If both vendors choose the same section, half of all fans buy from each vendor.

1. Construct a payoff matrix showing how many hotdogs each vendor sells for every pair of section choices. Underline all best responses.
2. Does either vendor have a dominant strategy? If so, is it strictly dominant? Explain.
3. Find all pure-strategy Nash equilibria of this game. Explain.

Solution. The payoffs are the numbers of hotdogs sold, with Vendor A's payoff listed first.

	Vendor B: S_1	Vendor B: S_2	Vendor B: S_3
Vendor A: S_1	(150, 150)	(100, <u>200</u>)	(150, 150)
Vendor A: S_2	(<u>200</u>, 100)	(<u>150</u>, <u>150</u>)	(<u>200</u>, 100)
Vendor A: S_3	(150, 150)	(100, <u>200</u>)	(150, 150)

Each vendor's dominant strategy is to set up in S_2. If the other vendor chooses an end section, choosing S_2 attracts 200 fans; if the other vendor chooses S_2, choosing S_2 sells 150 hotdogs rather than 100. So the unique pure-strategy Nash equilibrium is (S_2, S_2), where each vendor sells 150 hotdogs.

3 Constructing Games

Problem. For each of the following, either (i) give an example of the payoff matrix of a game with two players and three strategies per player that satisfies the requirement, or (ii) explain why the requirement is impossible to satisfy. Make all payoffs integers between 0 and 9, and underline the best responses in the payoff matrix. Do not choose examples of games covered in class, discussion, or in the textbook.

(a) One player receives the same payoff regardless of the strategies chosen, and neither player has a dominant strategy.

(b) There are exactly three pure-strategy Nash equilibria.

(c) One player has a strictly dominant strategy, and there are no pure-strategy Nash equilibria.

(d) One player has a dominant strategy, and there are exactly two pure-strategy Nash equilibria.

(e) One player has a strictly dominant strategy, the second player has a dominant strategy, and there are four pure-strategy Nash equilibria.

Solution.

(a) Impossible. The player whose payoff is constant is indifferent to all of their strategies, so each strategy is a (weakly) dominant strategy for that player, which contradicts the requirement that neither player have a dominant strategy.

(b) This is satisfied by a game with diagonal best outcomes:

	B 1	B 2	B 3
A 1	(<u>9</u>, <u>8</u>)	(0, 1)	(1, 2)
A 2	(0, 0)	(<u>8</u>, <u>9</u>)	(2, 3)
A 3	(1, 1)	(3, 4)	(<u>7</u>, <u>7</u>)

So the pure-strategy Nash equilibria are (A 1, B 1), (A 2, B 2), and (A 3, B 3).

(c) Impossible. A player with a strictly dominant strategy will choose it, and the other player will have at least one best response to that choice, which is a pure-strategy Nash equilibrium.

(d) For example:

	B 1	B 2	B 3
A 1	(<u>8</u>, <u>7</u>)	(<u>8</u>, <u>7</u>)	(<u>8</u>, 2)
A 2	(4, <u>9</u>)	(5, 1)	(6, 8)
A 3	(1, 1)	(2, <u>8</u>)	(3, 6)

A 1 is strictly dominant for A. Against A 1, B's best responses are B 1 and B 2, so the two pure-strategy Nash equilibria are (A 1, B 1) and (A 1, B 2).

(e) Impossible. A strictly dominant strategy limits one player's strategy to a single choice (row) in every pure-strategy Nash equilibrium. Since there are only three possible choices for the other player, there can be at most three distinct pure-strategy Nash equilibria, not four.

4 Nash Equilibrium Statements

Problem. Consider each of the following statements. Is the statement correct or incorrect? If you think it is correct, give a brief (1–3 sentence) explanation. If you think it is incorrect, give a counterexample of a game, together with a brief (1–3 sentence) explanation.

(a) If a pair of strategies gives both players higher payoffs than a pure-strategy Nash equilibrium, then it cannot be a Nash equilibrium.

(b) If a two-player game has a pure-strategy Nash equilibrium, then at least one player must be playing a dominant strategy in that equilibrium.

(c) If (s_A, s_B) is a pure-strategy Nash equilibrium and s_A is Player A's unique best response to s_B, then any other pure-strategy Nash equilibrium must have Player B choose a strategy other than s_B.

Solution.

(a) Incorrect. Consider the game

	B Left	B Right
A Up	$(1, 1)$	$(0, 0)$
A Down	$(0, 0)$	$(3, 3)$

Both (Up, Left) and (Down, Right) are Nash equilibria. The latter gives both players a higher payoff than the former, so a payoff-superior outcome can itself be a Nash equilibrium. Another example is the prisoners' dilemma, where the outcome (Cooperate, Cooperate) gives both players a higher payoff than the Nash equilibrium (Defect, Defect).

(b) Incorrect. In the following game, all three diagonal outcomes are Nash equilibria, but neither player has a dominant strategy:

	B 1	B 2	B 3
A 1	$(4, 3)$	$(0, 1)$	$(1, 0)$
A 2	$(0, 1)$	$(5, 4)$	$(1, 0)$
A 3	$(1, 0)$	$(0, 1)$	$(6, 5)$

Each player's best strategy changes with the other player's choice, so no strategy is dominant for either player.

(c) Correct. If B chose s_B in another equilibrium, A's unique best response would still be s_A, making the outcome the original (s_A, s_B). So any distinct equilibrium must have B choose a strategy other than s_B.

5 Parameterized Payoff Matrix

Problem. Consider the following game. The first payoff in each cell is Player 1's payoff, and the second is Player 2's payoff.

(a) Suppose x = 4 and y = 5. Find all pure-strategy Nash equilibria.

	Player 2: L	Player 2: C	Player 2: R
Player 1: U	(6, 8)	(2, 2)	$(1, x + y)$
Player 1: M	(3, 4)	(x, y)	(4, 3)
Player 1: D	(2, 1)	(3, 4)	$(7, y - x + 2)$

(b) Now allow x and y to vary. Find the range of x and the range of y for which (M,C) is a pure-strategy Nash equilibrium.

(c) Suppose Player 2 is exactly indifferent between L and R when Player 1 chooses U, and is exactly indifferent between C and R when Player 1 chooses D. Find x and y. At these values of x and y, find all pure-strategy Nash equilibria.

Solution.

(a) Substitute $x = 4$ and $y = 5$:

	L	C	R
U	$(6, 8)$	$(2, 2)$	$(1, 9)$
M	$(3, 4)$	$(4, 5)$	$(4, 3)$
D	$(2, 1)$	$(3, 4)$	$(7, 3)$

Player 1's best responses to L, C, and R are U, M, and D, respectively. Player 2's best responses to U, M, and D are R, C, and C, respectively. The only mutual best response is (M, C), so it is the unique pure-strategy Nash equilibrium.

(b) Against C, Player 1's payoffs from U, M, and D are 2, x, and 3, so M is a best response exactly when $x \geq 3$. Against M, Player 2's payoffs from L, C, and R are 4, y, and 3, so C is a best response exactly when $y \geq 4$. So (M, C) is a pure-strategy Nash equilibrium exactly for $x \geq 3$ and $y \geq 4$.

(c) Player 2's payoffs from L and R against U are 8 and $x + y$, so indifference requires $x + y = 8$. Against D, Player 2's payoffs from C and R are 4 and $y - x + 2$, so indifference requires $y - x = 2$. Solving the system

$$\begin{cases} x + y = 8, \\ y - x = 2 \end{cases}$$

gives $y = x + 2$, so substituting into $x + y = 8$ yields $x + (x + 2) = 8 \implies 2x = 6 \implies x = 3$. Then $y = x + 2 = 5$.

Solved matrix:

	L	C	R
U	$(6, 8)$	$(2, 2)$	$(1, 8)$
M	$(3, 4)$	$(3, 5)$	$(4, 3)$
D	$(2, 1)$	$(3, 4)$	$(7, 4)$

At these values, Player 1's best responses to L, C, and R are U; M and D; and D, respectively. Player 2's best responses to U, M, and D are L and R; C; and C and R, respectively. The pure-strategy Nash equilibria are therefore (U, L), (M, C), (D, C), and (D, R).
